===== Since WBE can be used to treat various types of wastewater, as presented in the previous section, it can be used as an effective method for wastewater treatment. Based on the above methods, there are two main types of newly developed membranes for wastewater treatment, as shown in [Figure 4](#ijerph-13-01223-f004){ref-type="fig"}: (1) High-performance membrane; and (2) Low-cost membrane. Because the membrane characteristics will be highly dependent on the type of membrane used, one could first consider the type of membrane to be used for the treatment of wastewater. Generally, WBE has higher permeability and better selectivity than reverse osmosis (RO), since it has a higher rejection rate of hydrated salts \[@B80-ijerph-13-01223]. As shown in [Figure 4](#ijerph-13-01223-f004){ref-type="fig"}, high-performance membranes, such as regenerated cellulose and polyamide membranes, cannot be used for WBE due to their high rejection rate of hydrated salts (greater than 99%) and a high cost of manufacture. High-performance membranes are used for the treatment of concentrated waste solution or highly saline brackish water, in addition to wastewater. However, low-cost membranes can be used for WBE due to their lower selectivity. Compared to traditional membranes, low-cost membranes possess the advantages of easy manufacture, low cost, and high permeability. These membranes are fabricated from polysulfone, polyethylene terephthalate, polypropylene, polyester, polycarbonate, or other polymer materials \[@B81-ijerph-13-01223]. Like traditional membranes, low-cost membranes have a rejection rate between 60%--97% \[@B82-ijerph-13-01223], which is generally higher than the rejection rate of RO for wastewater (35%).
