
Tree Vertex Splitting Problem Greedy Method

The greedy algorithm is efficient in providing an optimal solution to a problem. T is a subset of edges that form a tree that includes each vertex, where V is the set of vertices. The Greedy Tree algorithm allows you to find the shortest paths between any pair of trees with given weights. The algorithm consists of three steps: Step 1: Create a tree with as little complexity as possible. Step 2: Finding the shortest path between all pairs of vertices in the tree. Step 3: If the shortest path is found, then terminate the algorithm. If any path is longer than found, then it must be continued This may sound a bit vague, but all you're doing is creating a new tree.
